AMENDMENTS TO THE CLAIMS

1. (Currently amended) A network node apparatus <u>included in a plurality of node apparatuses connected via a transmission line, including a start node apparatus, and end node apparatus, and a center node apparatus, each node apparatus having an input terminal and an output terminal being each connected to said transmission line to form a bi-directional transmission path via said transmission line to another network node apparatus, comprising:</u>

a switching [[means]] <u>device</u> for switching a signal sent out via said transmission path from said another network node apparatus to be folded back and output to said another network node apparatus again;

a test signal sending component for sending out a test signal into said transmission path in response to occurrence of a fault in said transmission line or said another network node apparatus, whereby the test signal is sent from each of the start node apparatus and the end node apparatus of said transmission line to a center node apparatus; and

a determination device for determining the signal quality of the test signal by receiving the folded-back test signal,

whereby when said switching device is included in the center node
apparatus and switches the test signal sent out via said transmission path from each of
said start node apparatus and said end node apparatus to be folded back and output to
each of said start node apparatus and said end node apparatus again, and whereby
each of said start node and said end node having received the folded-back signal
identifies a fault location based on the determination result from the determination
device; and releases the nodes outside a fault interval in said transmission path, if there

Application No. 10/086,553 Amendment dated October 25, 2006

Reply to Office Action of July 25, 2006

is any fault detected in either said start node or said end node during the identification

operation.

2. (Original) The network node apparatus according to claim 1, further

Docket No.: Y2238.0035

comprising: means for demultiplexing a wavelength multiplexed signal entered from

said transmission line; and means for multiplexing the wavelength demultiplexed

signal again by exchanging said wavelength demultiplexed signal into a predetermined

route.

3. (Original) The network node apparatus according to claim 2, further

comprising wavelength conversion means for converting the wavelength of the signal

sent out from said another network node apparatus into the wavelength of said

wavelength demultiplexed signal.

4. (Cancelled)

5. (Original) The network node apparatus according to claim 3, further

comprising a test signal sending component for sending out a test signal into said

transmission path in response to occurrence of a fault in said transmission line or said

another network node apparatus, wherein said switching means switches the test signal

sent out via said transmission path from said another network node apparatus to be

folded back and output to said another network node apparatus again, and said

wavelength conversion means converts the wavelength of the test signal into the

wavelength of signal on said transmission line where the fault has occurred.

6. (Cancelled)

Amendment dated October 25, 2006

Reply to Office Action of July 25, 2006

7. (Currently amended) The network node apparatus according to claim [[6]]

Docket No.: Y2238.0035

1, wherein said determination means comprises a test signal receiving component for

receiving the test signal, and a determination portion for determining the presence or

absence of the fault by comparing the signal quality of the test signal received by said

test signal receiving component with a predetermined value.

8. (Currently amended) The network node apparatus according to claim

[[6]] 1, wherein said test signal sending component notifies the determination result of

said determination means to said another network node apparatus.

9. (Original) The network node apparatus according to claim 8, wherein said

test signal sending component transmits the test signal after notifying said

determination result.

10. (Currently amended) The network node apparatus according to claim

[[6]] 1, wherein said determination means measures at least one of BER (Bit Error Rate),

S (Signal)/N (Noise) ratio, the power of the test signal, and the wavelength of the test

signal as said signal quality.

11. (Original) The network node apparatus according to claim 1, wherein the

transparent transmission is performed.

12. (Currently amended) A network system comprising a plurality of

network node apparatuses connected via a transmission line, including a start node

apparatus, and end node apparatus, and a center node apparatus, each network node

apparatus having an input terminal and an output terminal being each connected to

said transmission line to form a bi-directional transmission path via said transmission

line to another network node apparatus, wherein said network system comprises:

Amendment dated October 25, 2006

Reply to Office Action of July 25, 2006

a test signal sending component for sending out a test signal into said transmission path in response to occurrence of a fault in said transmission line or said another network node apparatus, whereby the test signal is sent from each of the start node apparatus and the end node apparatus of said transmission line to a center node apparatus;

Docket No.: Y2238.0035

a switching [means] device for switching a signal sent out via said transmission path from said another network node apparatus to be folded back and output to said another network node apparatus again, wherein said switching means in the center node apparatus switches the test signal sent out via said transmission path from each of said start node apparatus and said end node apparatus to be folded back and output to each of said start node apparatus and said end node apparatus again;

determination means for determining the signal quality of the test signal by receiving the test signal at each of the start node apparatus and the end node apparatus,

whereby each of said start node and said end node having received the determination result identifies a fault location based on the determination result; and releases the nodes outside a fault interval in said transmission path, if there is any fault detected in either said start node or said end node during the identification operation.

13. (Original) The network system according to claim 12, wherein said network node apparatus comprises means for demultiplexing a wavelength multiplexed signal entered from said transmission line, and means for multiplexing the wavelength demultiplexed signal again by exchanging said wavelength demultiplexed signal into a predetermined route.

Application No. 10/086,553 Amendment dated October 25, 2006

Reply to Office Action of July 25, 2006

14. (Original) The network system according to claim 13, wherein said

Docket No.: Y2238.0035

network node apparatus further comprises wavelength conversion means for

converting the wavelength of the signal sent out from said another network node

apparatus into the wavelength of the wavelength demultiplexed signal.

15. (Cancelled)

16. (Original) The network system according to claim 14, wherein said

network node apparatus further comprises a test signal sending component for sending

out a test signal to said transmission path in response to occurrence of a fault in said

transmission line or said another network node apparatus, wherein said switching

means switches the test signal sent out via said transmission path from said another

network node apparatus to be folded back and output to said another network node

apparatus again, and said wavelength conversion means converts the wavelength of

the test signal into the wavelength of signal on said transmission line where the fault

has occurred.

17. (Currently amended) The network system according to claim [[15]] 12,

wherein said network node apparatus further comprises determination means for

determining the signal quality of the test signal by receiving the test signal to effect

transmission control over said test signal sending component in accordance with the

determination result.

18. (Original) The network system according to claim 17, wherein said

determination means comprises a test signal receiving component for receiving the test

signal, and a determination portion for determining the presence or absence of the fault

by comparing the signal quality of the test signal received by said test signal receiving

component with a predetermined value.

Application No. 10/086,553 Docket No.: Y2238.0035 Amendment dated October 25, 2006

Reply to Office Action of July 25, 2006

19. (Original) The network system according to claim 17, wherein said test

signal sending component notifies the determination result of said determination

means to said another network node apparatus.

20. (Original) The network system according to claim 19, wherein said test

signal sending component sends out the test signal after notifying said determination

result.

21. (Original) The network system according to claim 17, wherein said

determination means measures at least one of BER, S/N ratio, the power of the test

signal, and the wavelength of the test signal as said signal quality.

22. (Original) The network system according to claim 12, wherein said

network node apparatus makes the transparent transmission.

23. (Currently amended) A fault location detecting method for use in a

network system having a plurality of network nodes (hereinafter referred to as nodes)

connected via a transmission line, comprising steps for: sending out a test signal from a

terminal node of said transmission line to a working system path (current path) after

switching said working system path to an auxiliary system path (stand-by path) in

response to occurrence of a fault; folding back the test signal to said terminal node in a

node that has received the test signal; and determining the signal quality of the test

signal folded back to identify the fault location based on the determination result in

said terminal node, wherein said terminal node is each of a start node and an end node

of said transmission line.

24. (Cancelled)

Amendment dated October 25, 2006

Reply to Office Action of July 25, 2006

25. (Currently Amended) A fault location detecting method for use in a

network system having a plurality of nodes connected via a transmission line, the

method comprising steps for:

sending out a test signal from a terminal node of said transmission line to a

Docket No.: Y2238.0035

working system path (current path) after switching said working system path to an

auxiliary system path (stand-by path) in response to occurrence of a fault;

sending out the determination result to said terminal node by determining

the signal quality of the test signal in a node that has received the test signal;

identifying the fault location based on the determination result in said

terminal node that has received the determination result; and

sending out the test signal from the node having sent out the determination

result to said working system path if there is no fault detected during the operation of

the identifying step.

26. (Currently Amended) The fault location detecting method according to

claim 25, further comprising: -a step-for-extending the node for sending out the test

signal by every one hop in succession from the node having sent out said determination

result.

27. (Cancelled)

28. (Currently Amended) A fault location detecting method for use in a

network system having a plurality of nodes connected via a transmission line, the

<u>method</u> comprising steps for:

sending out a test signal from each of a start node and an end node of said transmission line to a node located in the center of a working system path (current path) after switching said working system path to an auxiliary system path (stand-by path) in response to occurrence of a fault;

folding back the test signal to each of said start node and said end node in the node located in the center of said working system path that has received the test signal;

identifying the fault location based on the determination result by determining the signal quality of the test signal folded back at each of said start node and said end node; and

releasing the nodes outside a fault interval in said working system path to set up the other path, if there is any fault detected in either said start node or said end node during the operation of the identifying step.

29. (Currently Amended) A fault location detecting method for use in a network system having a plurality of nodes connected via a transmission line, <u>the method</u> comprising steps for:

sending out a test signal from each of a start node and an end node of said transmission line to a node located in the center of a working system path (current path) after switching said working system path to an auxiliary system path (stand-by path) in response to occurrence of a fault;

sending out the determination result to each of said start node and said end node by determining the signal quality of the test signal in the node located in the center of said working system path that has received the test signal;

Docket No.: Y2238.0035

identifying a fault location based on the determination result at each of said

start node and said end node having received the determination result; and

releasing the nodes outside a fault interval in said working system path to set

up the other path, if there is any fault detected in either said start node or said end node

during the operation of the identifying step.

30. (Currently amended) The fault location detecting method according to

claim 23, further comprising a step for folding back a wavelength signal to said

terminal node after converting the wavelength of the test signal into the wavelength

signal on said transmission line where the fault has occurred in the node having

received the test signal.

31. (Cancelled)

32. (Original) The fault location detecting method according to claim 23,

further comprising-a step for extending the node for folding back the test signal by

every one hop in succession from said terminal node.

33. (Currently amended) The fault location detecting method according to

claim 23, further comprising steps for:

extending the node for folding back the test signal by every plural hops in

succession from said terminal node;

and reducing the number of hops for extending the node in the fault interval,

if there is any fault detected during the <u>extending</u> operation of the extending step.

Docket No.: Y2238.0035

34. (Currently amended) The fault location detecting method according to

claim 23, further comprising steps for:

extending the node for folding back the test signal by every one hop in

succession from said terminal node;

and folding back the test signal via the nodes outside said working system

path, if there is any fault detected during the extending operation of the extending step.

35. (Original) The fault location detecting method according to claim 23,

wherein the signal quality of the test signal is determining by measuring at least one of

BER, S/N ratio, the power of the test signal and the wavelength of the test signal.

36. (New) A network node apparatus having an input terminal and an

output terminal being each connected to a transmission line, which forms a bi-

directional transmission path via said transmission line to another network node

apparatus, comprising:

a determination device in said network node for determining the signal

quality of a received test signal from another network node sent into said transmission

path in response to occurrence of a fault;

a test signal sending component in said network node apparatus for sending

out a test signal into said transmission path;

wherein said test signal sending component notifies the determination result

of said determination device to said another network node apparatus and, if no fault is

identified, transmits the test signal to a next network node apparatus after notifying

said determination result.

Amendment dated October 25, 2006

Reply to Office Action of July 25, 2006

37. (New) The network node apparatus according to claim 36, wherein said

Docket No.: Y2238.0035

determination device comprises a test signal receiving component for receiving the test

signal, and a determination portion for determining the presence or absence of the fault

by comparing the signal quality of the test signal received by said test signal receiving

component with a predetermined value.

38. (New) The network node apparatus according to claim 36, wherein said

determination device measures at least one of BER (Bit Error Rate), S (Signal)/N (Noise)

ratio, the power of the test signal, and the wavelength of the first test signal as said

signal quality.

39. (New) The network apparatus according to claim 36, wherein said

network node apparatus further comprises determination means for determining the

signal quality of the test signal by receiving the test signal to effect transmission control

over said test signal sending component in accordance with the determination result.

40. (New) A network system comprising a network node apparatus having

an input terminal and an output terminal being each connected to a transmission line,

which forms a bi-directional transmission path via said transmission line to another

network node apparatus, comprising:

a determination device in said network node for determining the signal

quality of a received test signal from another network node sent into said transmission

path in response to occurrence of a fault;

a test signal sending component in said network node apparatus for sending

out a test signal into said transmission path;

Amendment dated October 25, 2006

Reply to Office Action of July 25, 2006

wherein said test signal sending component notifies the determination result

Docket No.: Y2238.0035

of said determination device to said another network node apparatus and, if no fault is

identified, transmits the test signal to a next network node apparatus after notifying

said determination result.

41. (New) The network node system according to claim 40, wherein said

determination means comprises a test signal receiving component for receiving the test

signal, and a determination portion for determining the presence or absence of the fault

by comparing the signal quality of the test signal received by said test signal receiving

component with a predetermined value.

42. (New) The network system according to claim 40, wherein said network

node apparatus further comprises determination means for determining the signal

quality of the test signal by receiving the test signal to effect transmission control over

said test signal sending component in accordance with the determination result.

43. (New) The network node system according to claim 40, wherein said

determination means measures at least one of BER (Bit Error Rate), S (Signal)/N (Noise)

ratio, the power of the test signal, and the wavelength of the first test signal as said

signal quality.

44. (New) The network node system according to claim 40, wherein said

determination device comprises a test signal receiving component for receiving the test

signal, and a determination portion for determining the presence or absence of the fault

by comparing the signal quality of the test signal received by said test signal receiving

component with a predetermined value.

Docket No.: Y2238.0035

45 (New). A network node apparatus included in a plurality of node apparatuses connected via a transmission line, including a start node apparatus, and end node apparatus, and a center node apparatus, each node apparatus having an input terminal and an output terminal being each connected to said transmission line to form a bi-directional transmission path via said transmission line to another network node apparatus, wherein said network node apparatus comprises:

a test signal sending component for sending out a test signal into said transmission path in response to occurrence of a fault in said transmission line or said another network node apparatus, wherein the test signal is sent from each of the start node apparatus and the end node apparatus of said transmission line to a center node apparatus;

a determination device for determining the signal quality of the test signal by receiving the test signal at the center node apparatus, whereby the center node apparatus sends the determination result to start node apparatus and the end node apparatus

whereby each of said start node and said end node having received the determination result identifies a fault location based on the determination result; and releases the nodes outside a fault interval in said transmission path, if there is any fault detected in either said start node or said end node during the identification operation.

46. (New) A network system comprising a plurality of network node apparatuses connected via a transmission line, including a start node apparatus, and end node apparatus, and a center node apparatus, each network node apparatus having an input terminal and an output terminal being each connected to said transmission

Amendment dated October 25, 2006

Reply to Office Action of July 25, 2006

line to form a bi-directional transmission path via said transmission line to another

network node apparatus, wherein said network node apparatus comprises:

a test signal sending component for sending out a test signal into said

Docket No.: Y2238.0035

transmission path in response to occurrence of a fault in said transmission line or said

another network node apparatus, wherein the test signal is sent from each of the start

node apparatus and the end node apparatus of said transmission line to a center node

apparatus; and

a determination device for determining the signal quality of the test signal by

receiving the test signal at the center node apparatus, whereby the center node

apparatus sends the determination result to start node apparatus and the end node

apparatus;

wherein each of said start node and said end node having received the

determination result identifies a fault location based on the determination result; and

releases the nodes outside a fault interval in said transmission path, if there is any fault

detected in either said start node or said end node during the identification operation.
